Workplace Supervisor Name	Rekha Negi Lama

Month Commencing: March Choose an item.	Logbook Number: Choose an item.6/12
Work During March 2026, my focus was the continued investigation and functional testing of CRM roles and their associated workflows. I covered two key roles this month which are Event Management and Nepal Front Desk. For the <i>Event Management</i>, this role is responsible for coordinating student involvement in company-hosted events, from initial invitation through to attendance tracking and post-event follow-up. Initially, during the testing of this role, I went through the permissions and restrictions. I got to know that this role does not have the ability to add new students to the CRM system, had no access to social media leads, and deletion of student profiles was restricted. The first and the last restrictions do seem to appear intentional, keeping the role focused specifically on event-related operations, but I couldn't help but notice how they do not have access to the social media leads, which is strange as events do have a high volume of students inquiring through social media, which I raised as a question to the team. I eventually found it was one to maintain data privacy and ensure role-base access control. To help understand this role better in how this role is used in a real operational context, I reached out with our event management department. They were a big help which helped me validate the workflow against the actual departmental procedures. While doing the testing, I found several bugs within this role. For example, the scroll button that was completely non-functional, it prevented the users access all the information. moreover, there were few buttons that directed to wrong page or gave error message which was interruption to the workflow. There were few UI and layout inconsistencies. Additionally, I found out that when applying the filter, the filter did not consistently restore the default view and gave an empty result until the page was manually refreshed. All these issues were documented in detail and reported accordingly. Apart from the CRM role testing, while I was doing the investigation and workflow testing, I came across a bug on the company website itself. There is a form where student can fill out their details, while filling out that form I notice even though the form was prompting the applicant to upload a supporting document there was no file upload rendered on the page. This resulted in a disruption in the workflow. I immediately communicated this to the relevant team and helped them identify the exact section for	

this issue. This immediately taken into and was taken care of as it directly impacts the student lead acquisition pipeline.

Second half of the month, I was testing the *Nepal Front Desk* role. If you compare these two roles, the front desk is quite simple and straightforward. This role focuses on the initial contact with the student. I conducted two workflows for this role: one is CRM creation and another is the follow-up process. Despite being a simpler role, I did identify two notable bugs. One was the list not being populated if you click on a certain section, and another was that it gave you an option to edit the university details, but when you clicked on it, it gave you an error while trying to save the edit. The fact that the edit option is visible despite the role not having permission to write is quite misleading and confusing. As always, this was properly documented and reported to the team.

I examined the architecture with an emphasis on how data is organised, stored, and synchronised across various components to guarantee a clear understanding of CRM data flows and enable consistency in system behaviour. In CRM, there are essentially three types of profiles: standard CRM, language CRM, and student CRM. Each has a distinct function and method of development. I discovered how authorisation was used throughout the role while I was examining. The capacity of two users to delete or change a profile varies based on the type of profile, even if they have the same assigned role. For example, a role may be able to delete a standard CRM profile but not edit a language CRM profile. This suggests that permission logic is enforced at the profile-type level rather than universally at the role level, which calls for additional review to make sure the performance structure is deliberate and clearly documented.

Additionally, I gained a better grasp of the communication between the CRM system and the company website. The Yii2 framework is used to develop the CRM platform, while the Laravel PHP framework is used to build the website. These two distinct server-side programs communicate with each other over a RESTful API layer. The Laravel application packages the form data and transmits it to a specified CRM API endpoint when a student completes and submits a form on the website. After receiving the request, the Yii2-based CRM verifies the incoming data and, if everything is properly formatted, automatically generates a new student CRM profile. This procedure makes it possible to enter student leads straight into the CRM without the need for staff members to manually enter data. In addition, I verified that the CRM's data is kept in a MySQL-based relational database management system. A number of normalised relational tables contain student profiles, lead records, event registrations, and interaction logs. Foreign key connections connect entities like students, counsellors, and events to one another. Knowing this database structure has helped me put some of the bugs and data synchronisation problems I've seen into context by enabling me to consider where the failure might be happening at the data layer in addition to what's going wrong on the frontend.

I was given a new assignment at the end of March: creating an extensive CRM user handbook for internal employees. The manual's goal is to standardise staff interactions with the system and shorten the time required to onboard new team members by offering

clear, step-by-step instructions for typical CRM procedures. Creating and maintaining student profiles across various CRM types, navigating role-specific dashboards, carrying out crucial procedures, and comprehending permission restrictions are just a few of the topics covered in the guidebook. I'm working to make sure the manual's content is correct, suitably detailed, and understandable to employees with different levels of technical expertise while it's still in the drafting stage.

Throughout the month, I continued to regularly attend stand-up meetings with management, where I reported the results of my testing and investigations and gave updates on my progress. In addition, I met with my supervisor one-on-one as planned each month to go over my work, evaluate my performance, and talk about areas where I might still improve. And I've been assisting with typical troubleshooting and related issues.

Reflection and Learning

In terms of the range and depth of what I was able to investigate and contribute to, March was really beneficial. Examining the CRM's internal architecture, which includes how the three profile types are organised, how permissions behave differently across them, and how the platform interacts with the company website via an API, provided me with a far more comprehensive understanding of how the system functions overall as opposed to just at the surface level I deal with during role testing.

It was particularly helpful to comprehend the API connectivity between the Yii2 CRM and the Laravel website. I would acknowledge, though, that it originally took me some time to understand the concept of API integration. It wasn't immediately evident to me how two different frameworks interact, and I had to go over several parts of the procedure several times before I felt comfortable enough to explain it.

The permission inconsistency I discovered across CRM profile types was also a reminder that system behaviour does not always correspond to what is published or assumed. Early in my testing this month, I made the mistake of assuming that behaviour observed in one profile type would be consistent across all three, resulting in some gaps in my original findings that I had to go back and fill. It has now taught me to be more disciplined in testing across multiple circumstances rather than taking the behaviour of one example as reflective of all cases.

I'm particularly thrilled to have been handed the CRM user handbook, however I'm also conscious that technical writing is an area in which I can improve. In my earliest drafts, I struggled to find the correct balance between being thorough and approachable to readers with varying levels of technical knowledge. This is something I'm currently working on, and I plan to improve as I continue through the process. Overall, March has

underlined the fact that growth during this placement does not always occur when things go easily, but rather when I have had to slow down, seek for help, or reconsider my assumptions.

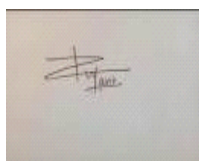

Summary and Future Focus

In March, I tested and researched the CRM roles for Nepal Front Desk and Event Management, carried out four workflows for both roles, found and documented a number of bugs in the CRM and on the company website, looked into the permission structure and profile architecture of the CRM, expanded my knowledge of the MySQL database layer and the website-to-CRM API integration, carried out general IT support, and started working on the CRM user manual.

In the future, I want to finish and polish the CRM user manual to a level appropriate for staff distribution. Additionally, I plan to investigate the bugs that were reported this month and, if I can, help resolve them.

Comments from Workplace Supervisor

Aparna was tasked with researching and testing two CRM positions in March: Nepal Front Desk and Event Management. She successfully finished both tasks. Her capacity to look beyond discrete system interactions and take into account the wider impact of errors on operational workflows is demonstrated by the numerous bugs she found in both jobs, including the missing document upload field on the business website. In particular, the website glitch was a good find because it wasn't only a visual problem but also had repercussions for the student lead pipeline. The way Aparna organises and presents her findings has improved. This month's problem documentation was more thorough and consistent than last month's, and she showed initiative and a more proactive approach to her job by contacting the Event Management department directly to check her workflow testing.

Nevertheless, there are several areas that require more work. In order to participate more independently to technical conversations, Aparna will need to continue gaining trust in her understanding of backend systems, particularly with regard to database operations and API behaviour. This month, there were also occasions when preliminary assumptions made while testing resulted in gaps that needed to be revisited. This emphasises the significance of taking a more thorough and rigorous approach from the beginning rather than changing course mid-investigation.

The CRM user manual assignment is a calculated move to help Aparna solidify her understanding and hone her technical communication abilities, both of which will be crucial as she advances. Early drafts indicate that she is still getting comfortable with technical writing, so this will be something to keep an eye on over the next month. All things considered, Aparna keeps growing steadily and is turning into a more dependable and involved team member. She is in a good position to assume more responsibility in the coming months if she maintains her concentration and pays attention to systematic working procedures.
